

# Socket Programming

---

Peerapon S.

CPE 314: Computer Networks (2/63)

## Topics

---

- ☐ Applications and transport layer services
- ☐ UDP socket
- ☐ TCP socket
- ☐ Concurrent communication
  
- ☐ Readings
  - ◆ Forouzan text: Ch. 2.1, 2.2, 2.5
  - ◆ Kurose text: Ch.2.7

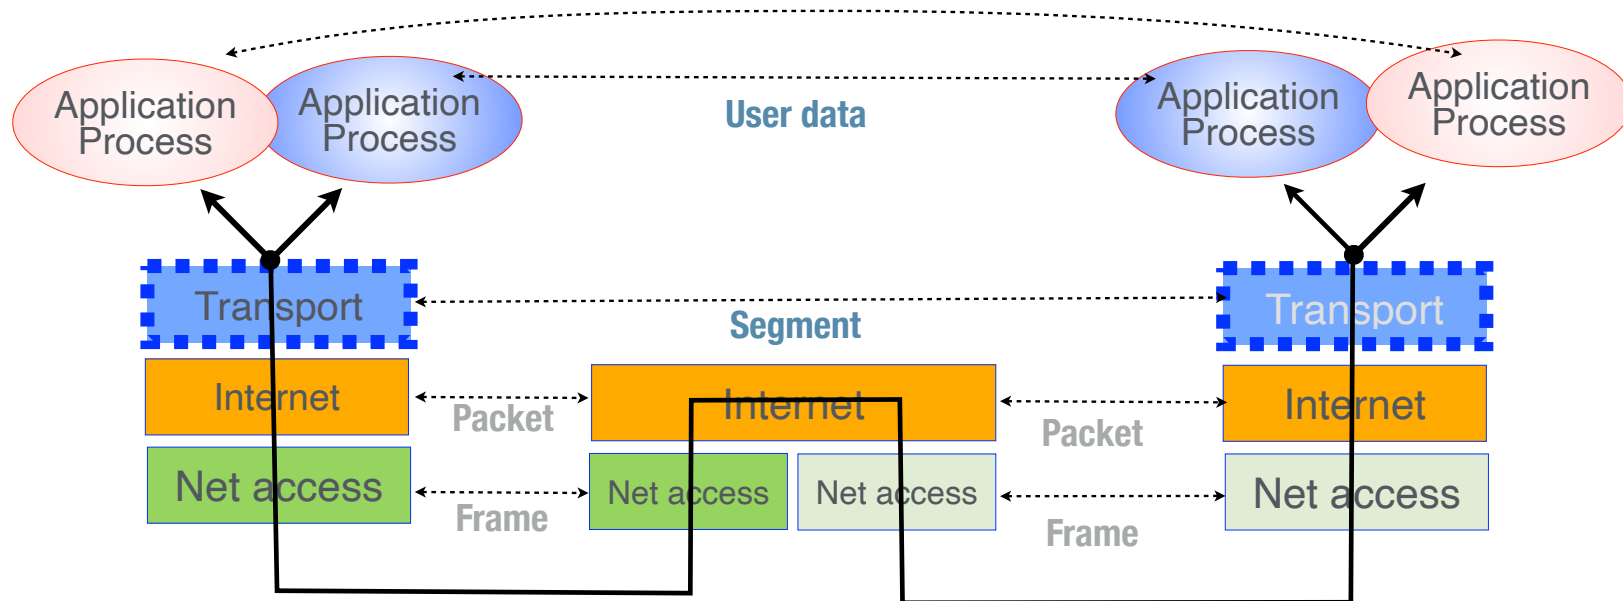

## Learning Objectives

---

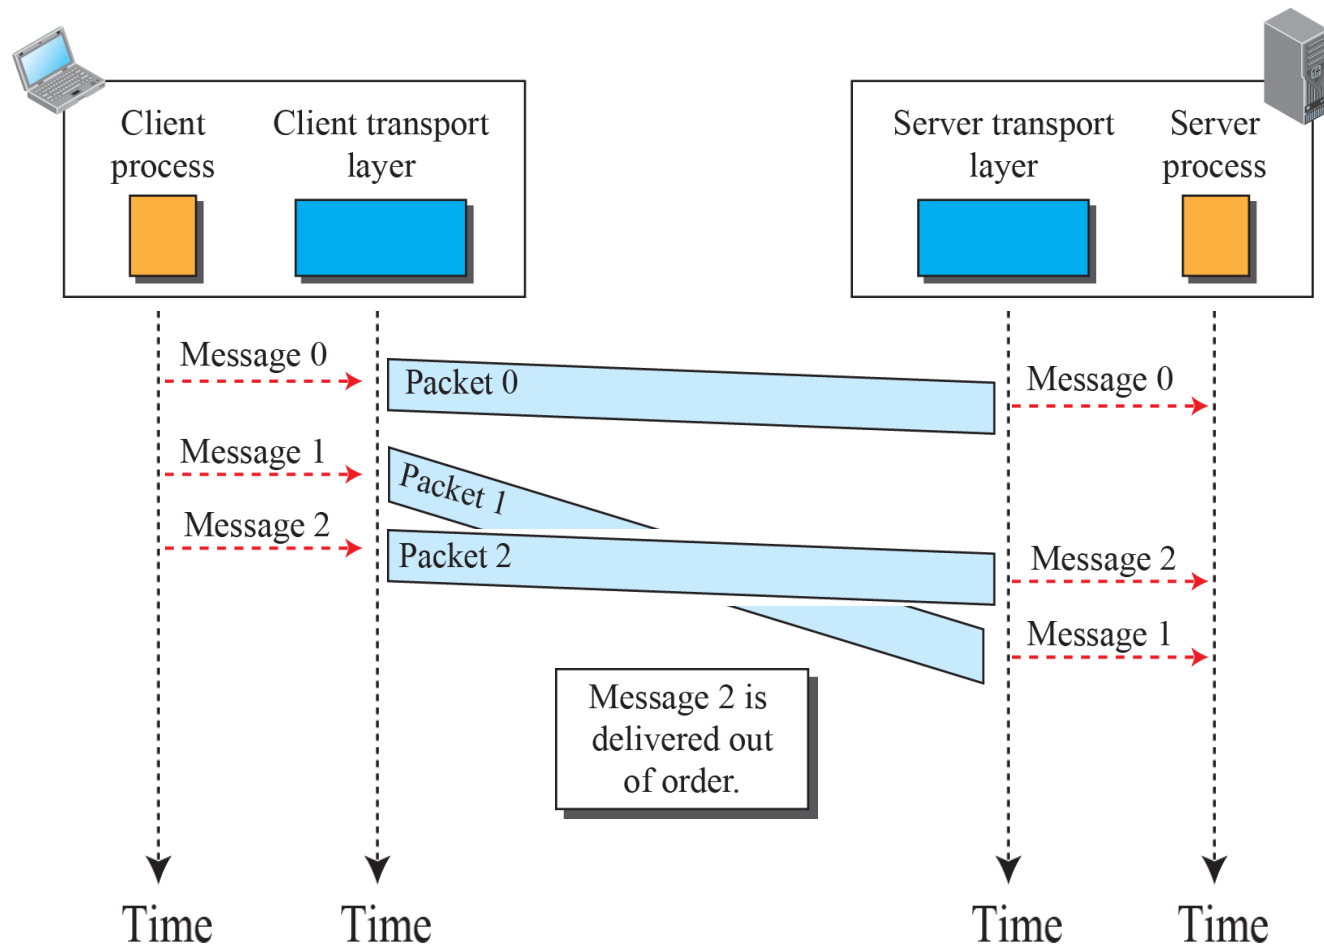

- ☐ Explain the services of transport layer
- ☐ Explain the meanings and roles of socket in network communication
- ☐ Explain the purpose of port number and port range.
- ☐ Explain the differences between UDP and TCP sockets
- ☐ Write a simple network program using UDP/TCP sockets.

## Transport Layer (TL) Services

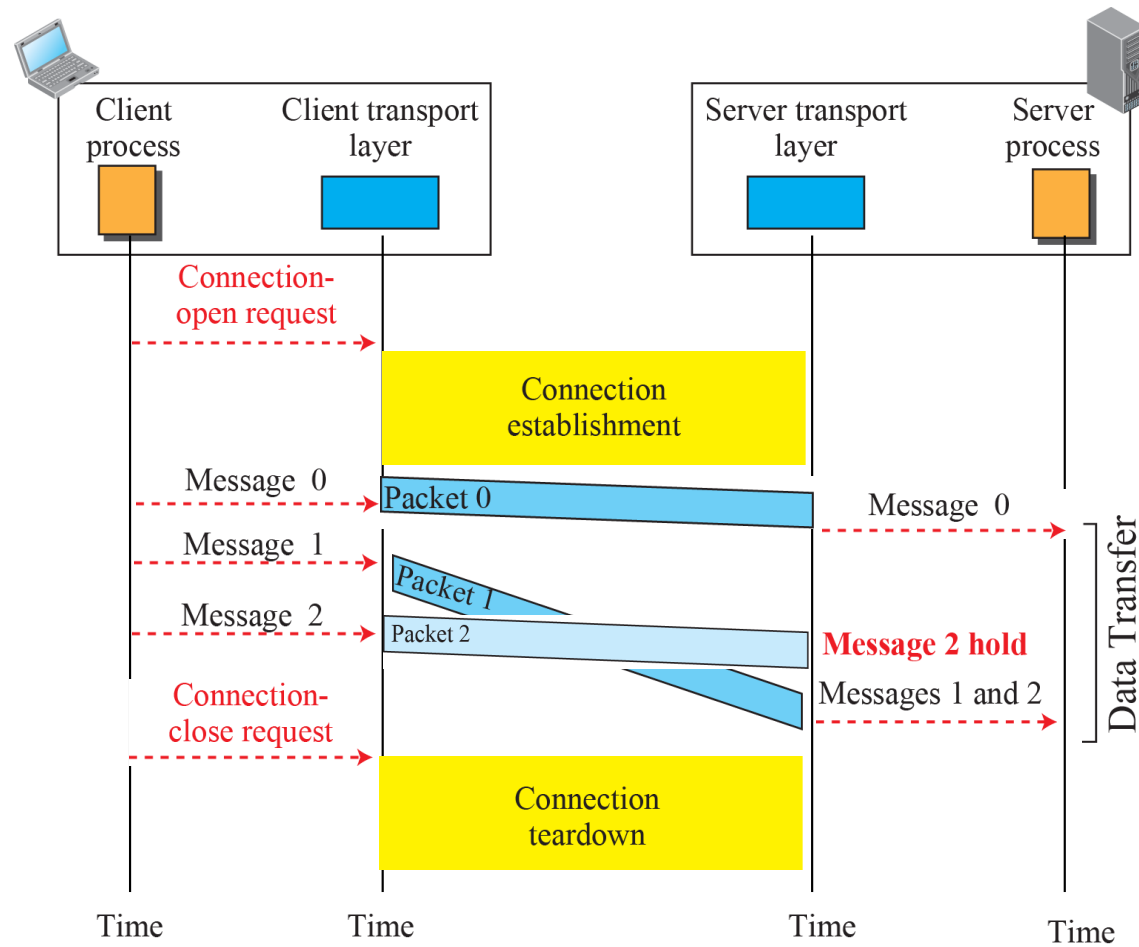

- Process-to-process message delivery service

## Connectionless Transport Service

## Connection-oriented Transport Service

## Two Main Internet Transport Layer Protocols

---

### ☐ UDP: User Datagram Protocol

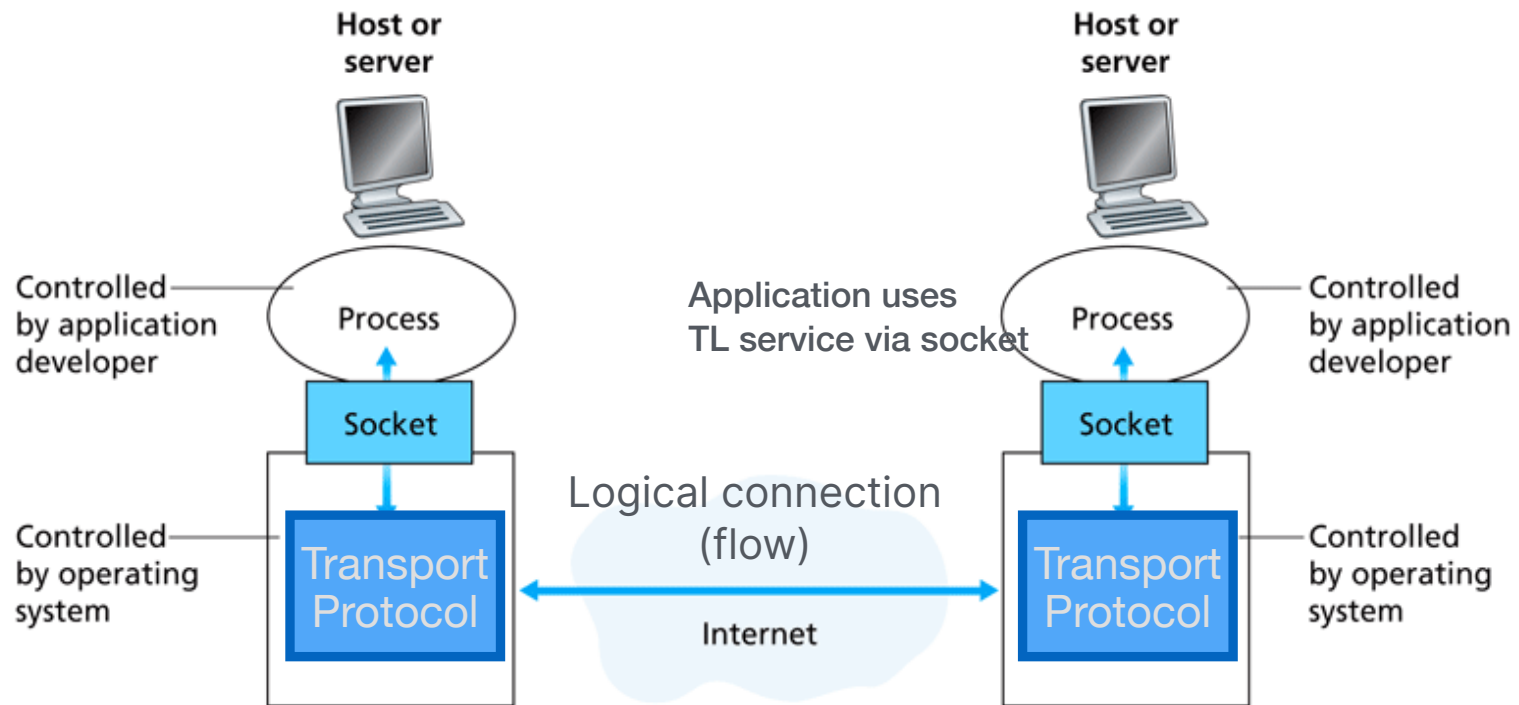

- ◆ Connection-less, Unreliable service
- ◆ Independent messages delivery

### ☐ TCP: Transport Control Protocol

- ◆ Connection-oriented, Reliable service
- ◆ Byte-stream delivery

	Loss-free	Order	No duplicate	Bound delay	Throughput
UDP					
TCP					

## Socket Abstraction

## Socket Address

(10.35.21.10, 56780)  
Web client application

(www.kmutt.ac.th, 80)  
Web server application

## Port Range for Server and Client

---

- Only some port numbers can be used by your custom app.

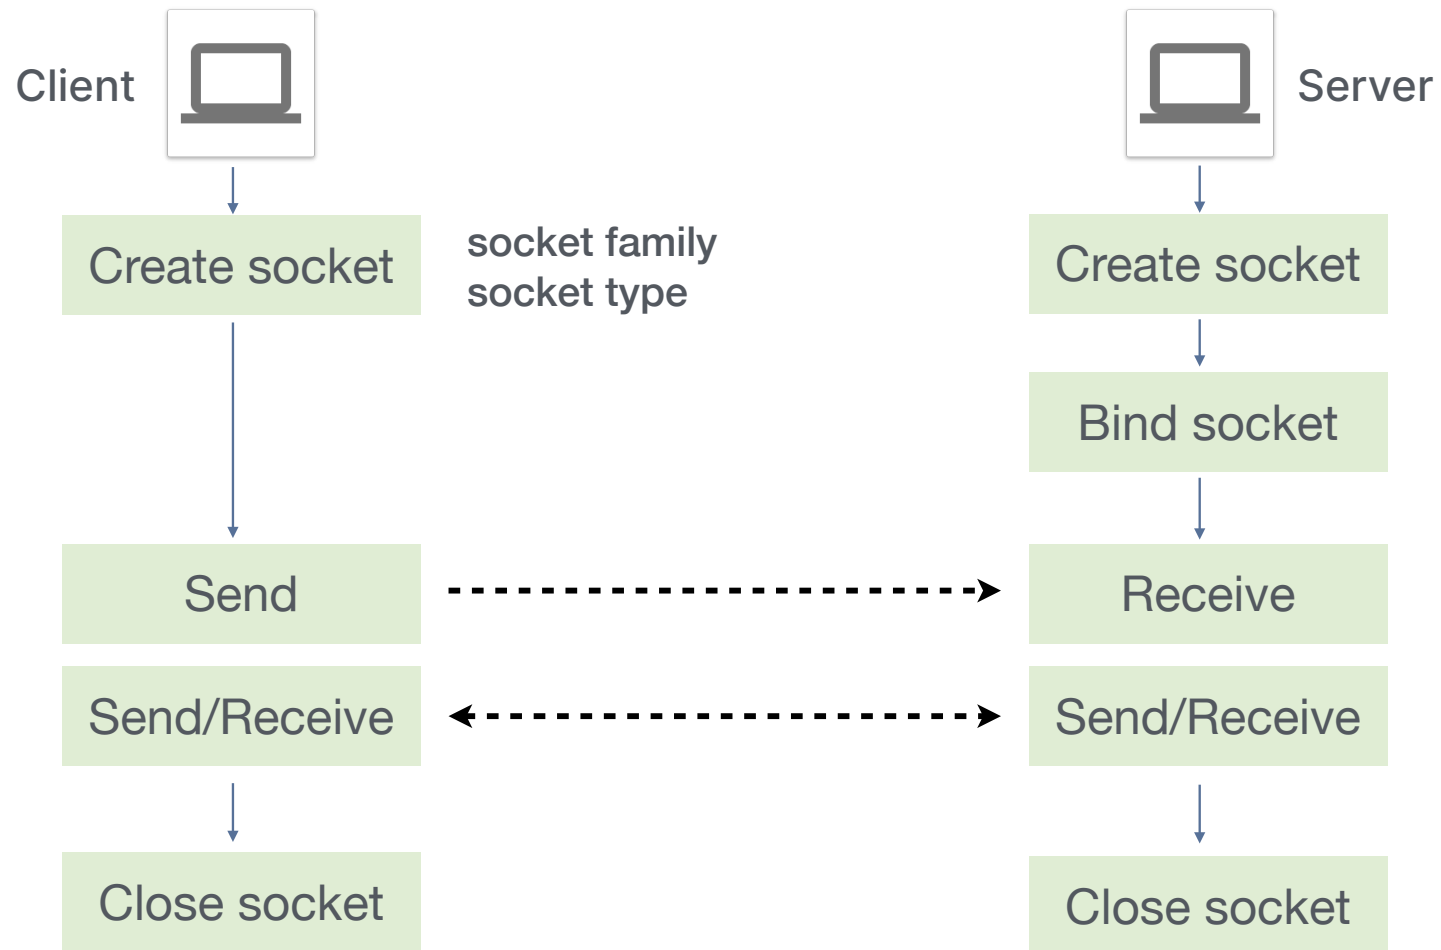

0 - 1023	1024 - 49,151	49,152 - 65,535
Well-known service ports	Registered ports	Ephemeral ports (dynamic, private, temporary)

	Local port	Remote port
Client side	Random from Ephemeral range	Service or Registered port
Server side	Service or Registered port	Derived from client segment

## UDP Program Demo

---

## Workflow of UDP Socket Communication

## UDP Server

---

```
from socket import *  
import sys
```

```
MAX_BUF = 2048      # Size of buffer to store received bytes  
SERV_PORT = 50000   # Server port number
```

```
addr = ('127.0.0.1', SERV_PORT)      # Socket address  
s = socket(AF_INET, SOCK_DGRAM)      # Create UDP socket  
s.bind(addr)                         # Bind socket to address  
print ('UDP server started ...')
```

Change to ' ' if running on MAC/Linux

```

while(1):
    print ('Client> ', end = '')
    txtin,addr = s.recvfrom(MAX_BUF) # txtin = received text
                                     # addr = client socket address
    print ('%s' %(txtin).decode('utf-8')) # Convert byte to string
    if txtin == b'quit':                # Break if user types 'quit'.
        print('Terminate server ...')
        break
    else:
        txtout = txtin.upper()          # Change text to upper case
        s.sendto(txtout, addr)          # Send it back to the client

```

Some key Python syntax rules:

- Indentation for code blocks
- ':' at the end of control statement.
- No variable declaration needed.

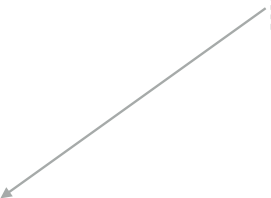

## UDP Client

```
from socket import *  
import sys
```

```
MAX_BUF = 2048
```

```
SERV_PORT = 50000
```

Change to remote server IP adress  
if not running in the same computer

```
addr = ('127.0.0.1', SERV_PORT) # Server socket address
```

```
s = socket(AF_INET, SOCK_DGRAM) # Create UDP socket
```

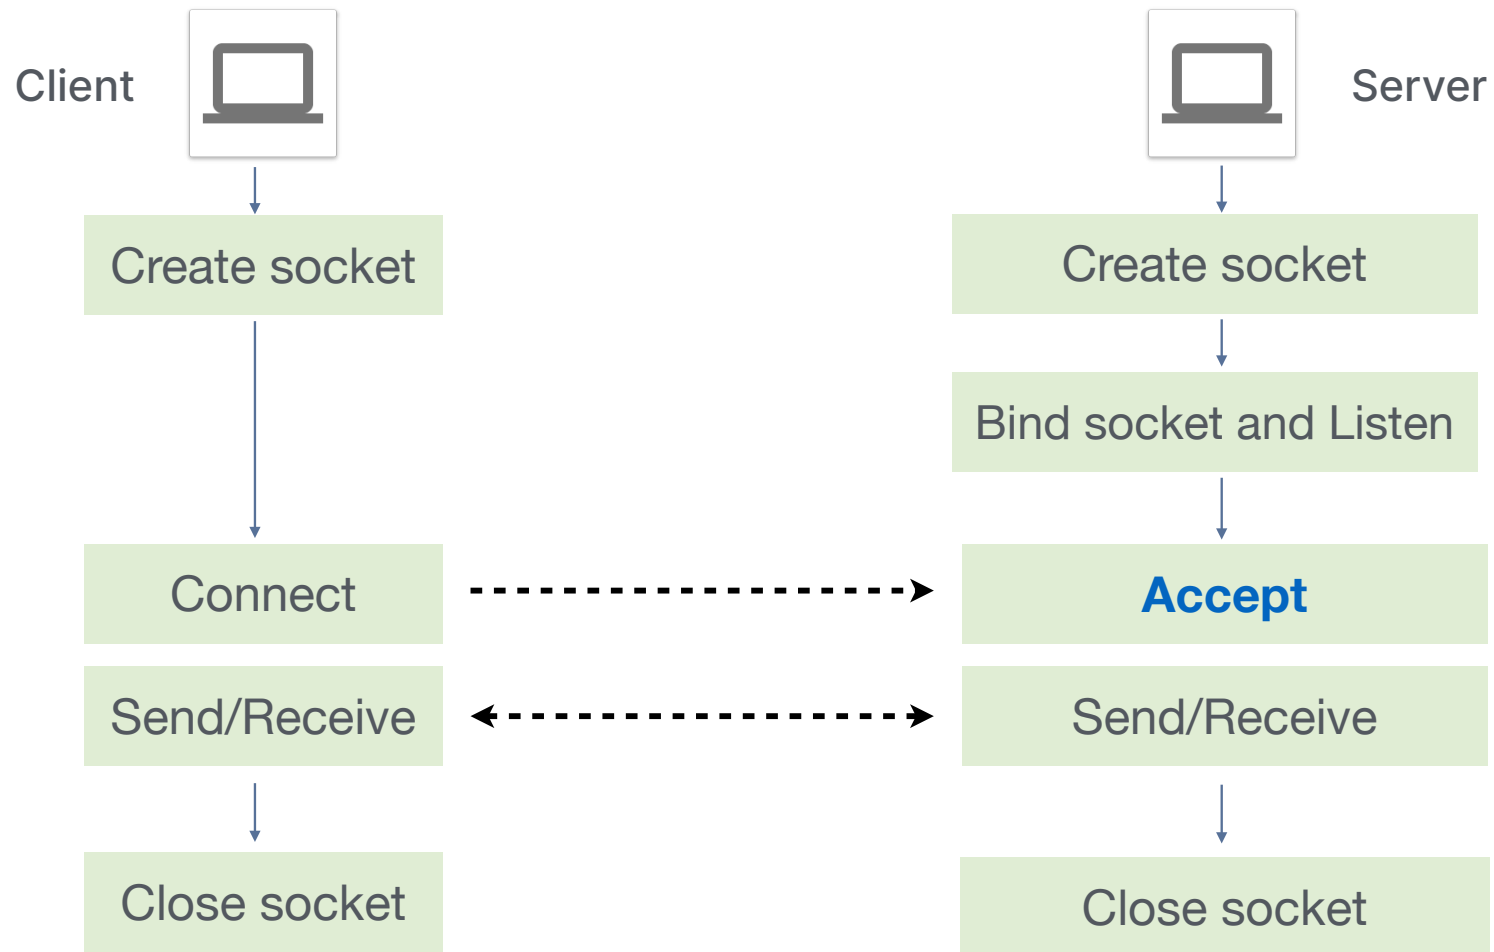

```
username = input('Enter your name: ') # text for prompt
while(1):
    print('%s> ' %(username), end='') # Print the prompt
    sys.stdout.flush()
    txtout = sys.stdin.readline().strip() # Take input from user keyboard
    s.sendto(txtout.encode('utf-8'), addr) # Convert to string to byte and send
    if txtout == 'quit':                # Exit if user types quit
        break
    modifiedMsg, srvAddr = s.recvfrom(2048) # Wait for modified text from server
    print (modifiedMsg.decode('utf-8'))     # Print the modified text.
```

## TCP Program Demo

---

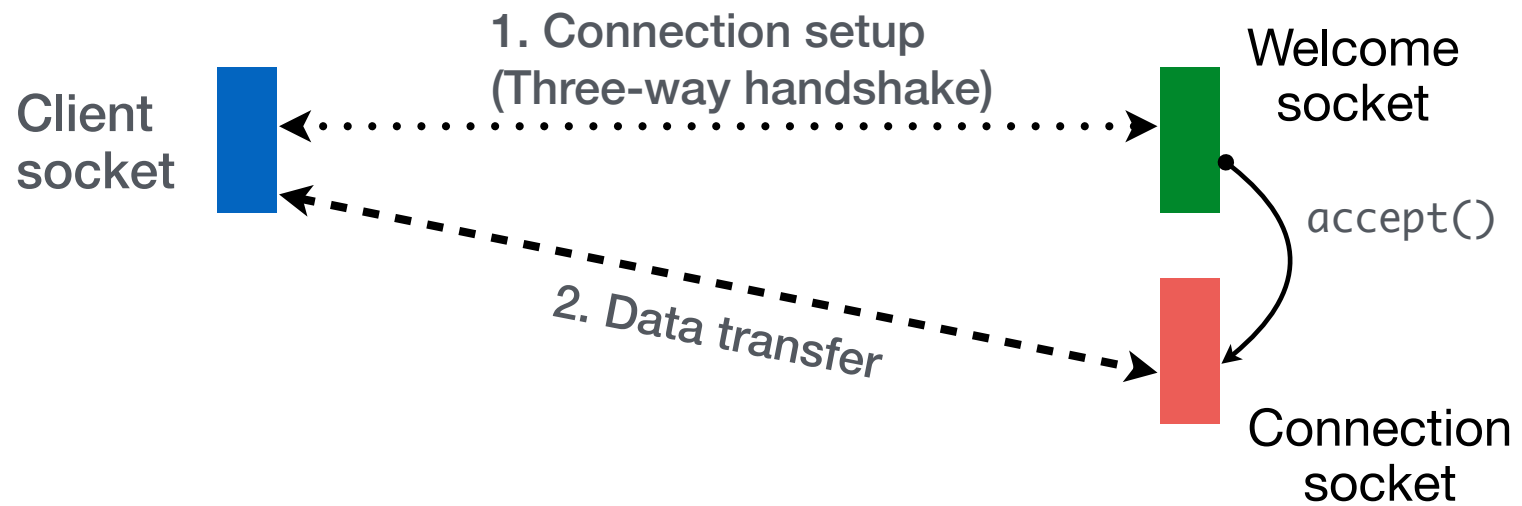

## Workflow of TCP Socket Communication

Client

Server

## TCP Server

```
from socket import *  
import sys
```

```
SERV_PORT = 50000
```

```
addr = ('127.0.0.1', SERV_PORT)  
s = socket(AF_INET, SOCK_STREAM)  
s.bind(addr)  
s.listen(1)  
print ('TCP server started ...')
```

```
while True:
```

```
sckt, addr = s.accept()
```

```
print ('New client connected ..')
```

```
while True:
```

```
    txtin = sckt.recv(1024)
```

```
    print ('Client> %s' %(txtin).decode('utf-8'))
```

```
    if txtin == b'quit':
```

```
        print('Client disconnected ..')
```

```
        print('Waiting for a new client ...')
```

```
        break
```

```
    else:
```

```
        txtout = txtin.upper()
```

```
        sckt.send(txtout)
```

```
sckt.close()
```

## TCP Client

```
from socket import *  
import sys
```

```
MAX_BUF = 2048
```

```
SERV_PORT = 50000
```

```
addr = ('127.0.0.1', SERV_PORT)
```

```
s = socket(AF_INET, SOCK_STREAM)
```

```
s.connect(addr)
```

```
username = input('Enter your name: ')
while True:
    print ('%s> ' %(username), end='')
    sys.stdout.flush()
    txtout = sys.stdin.readline().strip()
    s.send(txtout.encode('utf-8'))
    if txtout == 'quit':
        break
    modifiedMsg = s.recv(2048)
    print (modifiedMsg.decode('utf-8'))
```

Use 'netstat - a' to verify the TCP connection

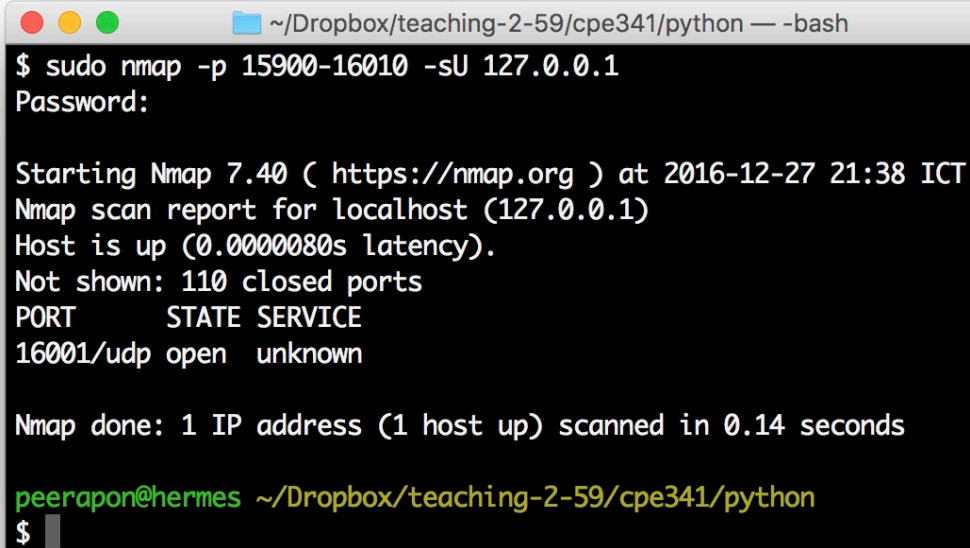

Note that TCP server does not quit when the client terminates.

- Scan open ports at a given IP address by using **nmap** utility (<https://nmap.org/download.html>)

```
# Scan port range 3000 to 4000 in local host for TCP server
nmap -p 3000-4000 127.0.0.1
```

```
# Scan port range 3000 to 4000 in local host for UDP server
nmap -p 3000-4000 -sU 127.0.0.1
```

```
# Same as above but does not ping before scanning
nmap -P0 -p 3000-4000 -sU 127.0.0.1
```

A terminal window with a title bar showing the path ~/Dropbox/teaching-2-59/cpe341/python and the shell -bash. The terminal displays the command \$ sudo nmap -p 15900-16010 -sU 127.0.0.1, followed by a password prompt. The output shows the Nmap version (7.40), the scan target (localhost 127.0.0.1), and the results: 110 closed ports and one open port at 16001/udp. The scan was completed in 0.14 seconds. The prompt changes to peerapon@hermes.

```
~/Dropbox/teaching-2-59/cpe341/python — -bash
$ sudo nmap -p 15900-16010 -sU 127.0.0.1
Password:

Starting Nmap 7.40 ( https://nmap.org ) at 2016-12-27 21:38 ICT
Nmap scan report for localhost (127.0.0.1)
Host is up (0.0000080s latency).
Not shown: 110 closed ports
PORT      STATE SERVICE
16001/udp open  unknown

Nmap done: 1 IP address (1 host up) scanned in 0.14 seconds

peerapon@hermes ~/Dropbox/teaching-2-59/cpe341/python
$
```

## Concurrent Connections

- ❑ Server almost always serves multiple clients simultaneously.
- ❑ Use either threaded or forked processes to handle new connections.

See SocketServer module in <https://docs.python.org/3/library/socketserver.html>

## Threaded Server

```
from socket import *
from threading import Thread
import os,sys

SERV_PORT = 50000

def handle_client(s):
    while True:
        txtin = s.recv(1024)
        print ('Client> %s' %(txtin).decode('utf-8'))
        if txtin == b'quit':
            print('Client disconnected ...')
            break
        else:
            txtout = txtin.upper()
            s.send(txtout)
    s.close()
    return
```

```
while True:
```

```
    sckt, addr = s.accept()
```

```
    ip, port = str(addr[0]), str(addr[1])
```

```
    print ('New client connected from ..' + ip + ':' + port)
```

```
try:
```

```
    Thread(target=handle_client, args=(sckt,)).start()
```

```
except:
```

```
    print("Cannot start thread..")
```

```
    import traceback
```

```
    traceback.print_exc()
```

## Forked Server

```
import os
from socket import *

s = socket(AF_INET, SOCK_STREAM)
s.bind(("", 5000)); s.listen(5)

while True:
    sckt, addr = s.accept()
    if os.fork() == 0: # child process ..
        ...
        sckt.close(); os._exit(0);
    else: # Parent process
        sckt.close()
s.close()
```

## Conclusion

---

- ☐ UDP and TCP sockets to access transport layer services (unreliable / reliable services)
- ☐ Port numbers to locally identify a network process
- ☐ Socket address to globally identify a network process.
- ☐ Different workflows in functions calls for UDP and TCP sockets.
- ☐ Concurrent connections achieved by using threaded or forked TCP servers.
